

LOG ANALYSIS AND SECURITY MONITORING

Name: Deeksha K

Internship: Cybersecurity Internship – Cognetix Technology

Tool Used: Windows Event Viewer

Platform: Windows Operating System

Introduction

Log analysis is an important part of cybersecurity monitoring. System logs record events such as user logins, system activities, and security alerts. By analyzing logs, security professionals can detect suspicious behavior, unauthorized access attempts, and potential security incidents.

Objective

The objective of this project is to analyze system security logs and identify important security events that may indicate suspicious activity.

Tools Used

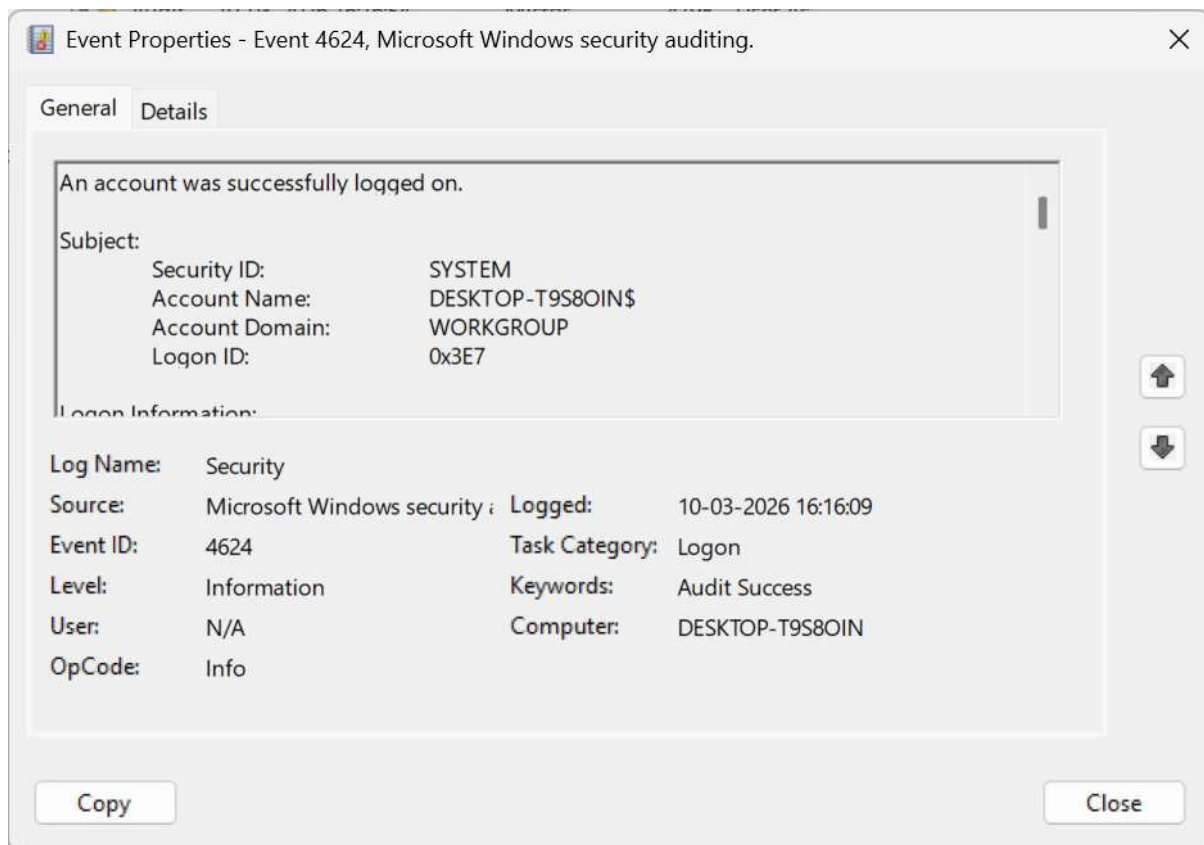

The tool used for this project is Windows Event Viewer.

Methodology

First, Windows Event Viewer was opened to access system logs. The Security log section was examined to view events related to authentication and system activity. Various event IDs were analyzed to understand the types of events being recorded.

Results

The log analysis revealed several system events including successful login attempts and security-related activities. These logs help track user activity and detect abnormal system behavior.

Security Analysis

Monitoring system logs is critical for identifying potential security threats. Failed login attempts or unusual activity patterns can indicate possible unauthorized access attempts.

Conclusion

Log analysis helps organizations monitor system activity and detect security incidents. Regular log monitoring improves overall system security and helps detect suspicious activities early.
